The code that was given in infection.txt creates a fork bomb in the C language. The “for (;;)” line makes an infinite loop. The “system” function works as if it were writing its argument to a terminal. The “argv[0]” argument takes the first argument that was used when running the program, which runs the program itself. When it is all put together, it makes an infinite number of copies of the current process, which in turn make copies of the current process. This program slows down the computer until it causes it to crash. This can be used by attackers to crash systems and thus deny service to users. Methods of defense include: using virtual machines to run untrusted code, setting resource allocation limits for active processes, and screening for common exploits in code.
